

# Cl0p Ransomware Targets Linux Systems with Flawed Encryption | Decryptor Available

---

 [sentinelone.com/labs/cl0p-ransomware-targets-linux-systems-with-flawed-encryption-decryptor-available/](https://sentinelone.com/labs/cl0p-ransomware-targets-linux-systems-with-flawed-encryption-decryptor-available/)

Antonis Terefos

## Executive Summary

---

- SentinelLabs has observed the first Linux variant of Cl0p ransomware.
- The ELF executable contains a flawed encryption algorithm making it possible to decrypt locked files without paying the ransom.
- SentinelLabs has published a free decryptor for this variant [here](#).

## Background

---

SentinelLabs observed the [first ELF variant of Cl0p](#) (also known as Cl0p) ransomware variant targeting Linux systems on the 26th of December 2022. The new variant is similar to the Windows variant, using the same encryption method and similar process logic.

The mentioned sample appears to be part of a bigger attack that possibly occurred around the 24th of December against a University in Colombia ([sample1](#), [sample2](#), [sample3](#), [sample4](#), [sample5](#)). On the [5th of January](#) the cybercrime group leaked victim's data on their onion page.

## ELF Technical Analysis

---

The ELF Cl0p variant is developed in a similar logic to the Windows variant, though it contains small differences mostly attributed to OS differences such as API calls. It appears to be in its initial development phases as some functionalities present in the Windows versions do not currently exist in this new Linux version.

A reason for this could be that the threat actor has not needed to dedicate time and resources to improve obfuscation or evasiveness due to the fact that it is currently undetected by all 64 security engines on [VirusTotal](#). [SentinelOne Singularity](#) detects Cl0p ransomware on both Linux and Windows devices.

THREAT FILE NAME <code>elfclop_elf.bin</code>		<a href="#">Copy Details</a>	<a href="#">Download Threat File</a>
Path	<a href="#">/home/admin1/Downloads/x/elfclop_elf.bin</a>	Initiated By	Agent Policy
Command Line Arguments	<code>./elfclop_elf.bin</code>	Engine	SentinelOne Cloud
Process User	<code>root</code>	Detection type	Static
Publisher Name	N/A	Classification	Infostealer
Signer Identity	N/A	File Size	1.19 MB
Signature Verification	N/A	Storyline	Static Threat - View in DV
Originating Process	<code>gnome-terminal-server</code>	Threat Id	1595133505043764355
SHA1	46b02cc186b85e11c3d59790c3a0bfd2ae1f82a5		

## SentinelOne Singularity detects Cl0p Linux ransomware

Initially, the ransomware creates a new process by calling `fork` and exits the parent-process. The child-process sets its file mode creation mask to any permission (read, write, execute) by calling `umask(0)`. It then calls `setsid`, creates a session and sets the process group ID. It tries to access root by changing the working directory to `"/` (`chdir("/")`). Once the permissions are set, the ransomware proceeds encrypting other directories.

## Targeted Folders & Files

While the Windows versions contain a hashing algorithm in order to avoid encrypting specific folders and files, such functionality was not observed in the Linux variant. The ELF variant targets specific folders, subfolders and all files/types.

The discovered ELF sample targets files contained in the following directories for encryption, though we do not exclude the possibility of future versions including more directories.

Folder	Description
<code>/opt</code>	Contains subdirectories for optional software packages
<code>/u01</code>	Oracle Directory, mount point used for the Oracle software only.
<code>/u02</code>	Oracle Directory, used for the database files.
<code>/u03</code>	Oracle Directory, used for the database files.
<code>/u04</code>	Oracle Directory, used for the database files.
<code>/home</code>	Contains the home directory of each user.
<code>/root</code>	Contains the home directory of the root user.

## Encryption Flaw

Windows versions of CI0p ransomware use a Mersenne Twister PRNG (MT19937) to generate a **0x75** bytes size RC4 key for each file. This key is then validated (checks if the first five bytes are NULL) and used for file encryption. Then, by using the RSA public key, it encrypts the generated RC4 key and stores it to `$filename.$clop_extension`. Victims who pay the ransom demand receive a decryptor which decrypts the generated CI0p file using the RSA private key, retrieves the generated RC4 key, and then decrypts the encrypted file.

This core functionality is missing in the Linux variant. Instead, we discovered a flawed ransomware-encryption logic which makes it possible to retrieve the original files without paying for a decryptor.

The Linux variant contains a hardcoded RC4 “master-key” which, during the execution of the main function, is copied into the global variable `szKeyKey`.

Sample’s RC4 “master-key”:

```
Jfkdskfku2ir32y7432uroduw8y7318i9018urewfdzZ20aifwuieh--cudsffdsd
```

During the file encryption phase, the ransomware – similar to the Windows version – generates a **0x75** bytes size RC4 key, with the use of a lookup table and a PRNG byte. This generated RC4 key is used to encrypt the mappedAddress and write it back to the file.

Then by using the RC4 “master-key” the ransomware encrypts the generated RC4 key and stores it to `$filename.$clop_extension`. By using a symmetric algorithm (second RC4) to “encrypt” the file’s RC4 key, we were able to take advantage of this flaw and decrypt CI0p-ELF encrypted files.

```
memset((int)rc4_key, 0, sizeof(rc4_key));
for ( index = 0; index <= 116; ++index ) // generate 0x75 RC4 key
    rc4_key[index] = lookup_table[randx()]; // Mersenne Twister PRNG
_rc4Full(rc4_key, 0x75u, mappedAddressPointer, fileSize); // encrypt file using generated RC4 key
keyLength = strlen(szKeyKey) + 1;
keyLength_m1 = keyLength - 1;
_rc4Full(szKeyKey, keyLength - 1, rc4_key, 0x75u); // encrypt generated RC4 key using RC4 "master-key"
Createkey(pathname, (unsigned __int8 *)rc4_key); // Create key file, $filename.$clop_extension
return munmap(mappedAddressPointer, fileSize); // "write" encrypted filebuffer
```

CI0p-ELF encryption flaw

CI0p-ELF Decryption Logic:

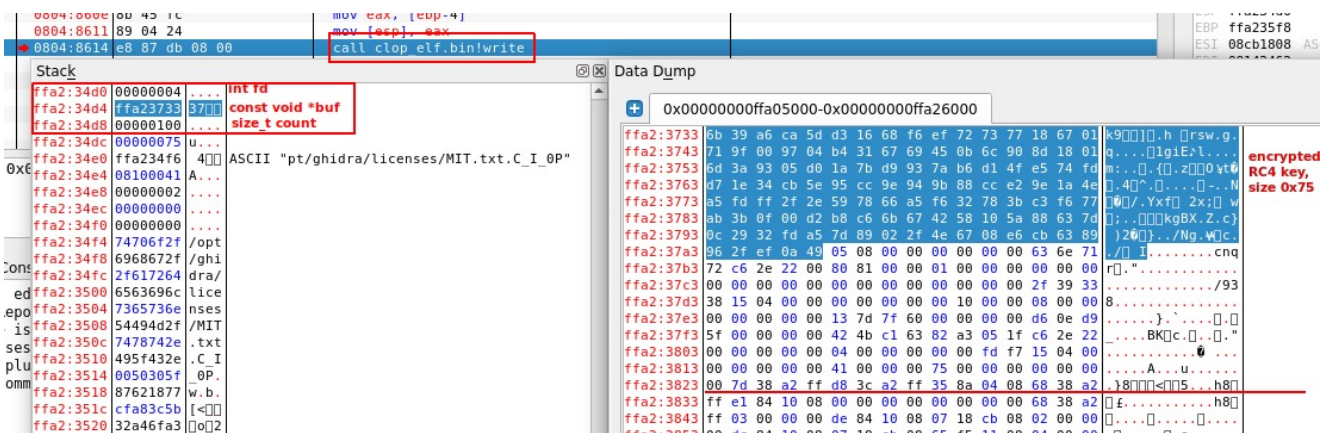

1. Retrieve RC4 “master-key”.
2. Read all `$filename.$clop_extension`.
3. Decrypt with RC4 using the RC4 “master-key”, the generated RC4 key.
4. Decrypt `$filename` with RC4 using the generated RC4 key.
5. Write decrypted to `$filename`.

We packed all this logic into the following Python script.

## ClOp File-Key Creation Flaw

The **0x75** bytes size PRNG RC4 key is encrypted with RC4 using the RC4 “master-key”. The encrypted RC4 output is **0x75** bytes size, though writes **0x100** bytes into the created ClOp key `$filename.$clon_extension`. This results in writing memory data to the file and more specifically stack variables.

ClOp-ELF file-key creation flaw.

This flaw provides some information regarding the file before encryption. This includes:

- File `fstat64` result
  - total size, in bytes, file size (`st_size`)
  - time of last status change, exact time of file encryption (`st_ctime`)
  - and more forensics information regarding the file before the encryption.
- Size of buffer for file encryption (with check of `>= 0x5f5e100` )

- RC4 “master-key” size
- RC4 PRNG key size

```

struct clopelfkeyfile {
    byte encr_rc4key[117]; // encrypted RC4 PRNG key, size 0x75 bytes
    stat fdstat; // stat(fd, &fdstat), size 0x58 bytes
    long fdid; // file node unique id, size 0x8 bytes
    int fd; // file descriptor, size 0x4 bytes
    int fdmappedaddr; // file mapped address, size 0x4 bytes
    off_t fdsize; // file size, size 0x8 bytes
    int rc4_msize; // RC4 "master-key" size, size 0x4 bytes
    long rc4_fsize; // RC4 PRNG key size, size 0x8 bytes
    int fdnameaddr; // filename string address, size 0x4 bytes
    int frameaddr; // frame pointer address, size 0x4 bytes
    int retaddr; // function return address, size 0x4 bytes
    byte fdpathaddr[3]; // part of filepath strings address, size 0x3 bytes
}

```

## Developed Functions & Names

---

In ELF binaries the `.symtab`, [Symbol Table Section](#), holds information needed to locate and relocate a program’s symbolic definitions and references, allowing us to retrieve function and global variable names.

Function Name	Description
<code>do_heartbeat(void)</code>	Main function which starts the encryption of various folders.
<code>find(char *,char const*)</code>	Multiple calls of this function are done by <code>do_heartbeat</code> ; this function takes as parameter 1) the starting folder to encrypt (example, “/opt”) 2) regex of files to encrypt (example, “*.*”) and performs a recursive search from the starting folder until encrypts the “matching” regex files.
<code>CreateRadMe(char *)</code>	This function takes as parameter the folder to create the ransom note.
<code>EncrFile(char *)</code>	Encrypts given filepath.
<code>existsFile(char *)</code>	Checks if File exists, or if the process has the permissions to open.
<code>_rc4Full(void const*,ushort,void *,ulong)</code>	Wrapper function to <code>_rc4Init</code> and <code>_rc4</code> , which is used to encrypt a buffer with a given key.
<code>Createkey(char *,uchar *)</code>	Creates and writes into “%s.C_I_0P” the encrypted buffer.

Global Variable	Description
szKeyKey	Global variable of 0x64 bytes size, initialized during main function, containing RC4 “master-key” which encrypts the “randomly” generated 0x75 bytes size RC4 key.

## Differences to Windows Variant

Rather than simply port the Windows version of Cl0p directly, the authors have chosen to build bespoke Linux payloads. We understand this to be the primary reason for the lack of feature parity between the new Linux version and the far more established Windows variant.

SentinelLabs expects future versions of the Linux variant to start eliminating those differences and for each updated functionality to be applied in both variants simultaneously.

Some of the differences worth highlighting are detailed below:

Differences	Description
Files/Folders exclusions	The Windows variant contains a hashing algorithm which excludes specific folders and files from encryption. This functionality was not observed in the Linux variant.
Extension exclusions	The Windows variant contains a hardcoded list of extensions to exclude from encryption. This functionality was not observed in the Linux variant.
Different methods of Reading/Writing depending on file size.	The Windows variant, depending on the size of the file, will choose different methods of reading a file and writing the encrypted buffer. Small files are ignored, medium-sized files will make use of <u>ReadFile/WriteFile</u> , large files will use <u>CreateFileMappingW/MapViewOfFile/UnmapViewOfFile</u> . The Linux variant encrypts all the files using <u>mmap64/munmap</u> . Both variants only encrypt the first 0x5f5e100 bytes of large files.
Ransom Note Decryption	The Windows variant stores the encrypted ransom note as a resource and decrypts it with a simple XOR algorithm. The Linux variant stores the note as plain text in “.rodata”.
Drive enumeration	The Windows variant initially enumerates through drives in order to “find” the starting point to recursively encrypt the folders. The Linux variant contains hardcoded “starting” folders.
RC4 default Key	Once the Windows variant generates a 0x75 size PRNG RC4 Key, it will check if the first 5 bytes are NULL; if so, it uses the default key for encryption. The Linux version does not perform this validation and does not contain a default RC4 key in case the first 5 bytes of the PRNG RC4 are NULL.

---

Command Line Parameters	The Windows variant can be executed in three ways: 1) without parameters encrypting all local and network drives, 2) with “runrun” parameter encrypting only network drives, 3) with a file as parameter which contains the folders to be encrypted (observed temp.ocx/temp.dat). The Linux variant does not accept command line parameters and recursively encrypts the specified hardcoded folders.
RC4 Key Encryption	The Windows variant encrypts the generated RC4 key responsible for the file encryption using the asymmetric algorithm RSA and a public key. In the Linux variant, the generated RC4 key is encrypted with a RC4 “master-key” (flawed logic).

---

## Ransom Notes

---

The Linux variant of Clop ransomware drops a ransom note on victim machines with a `.txt` format.

(use TOR browser)

ELF sample ransom note, “README\_C\_I\_OP.TXT”.

This differs somewhat from the Windows `.rtf` ransom note, although both use the email addresses `[email protected].[.]com` and `[email protected].[.]com` as ways for victims to contact the attackers.

(use TOR browser)

Window samples ransom note, “!\_READ\_ME.RTF”.

## Conclusion

---

Over the last twelve months or so we have continued to observe the increased targeting of multiple platforms by individual ransomware operators or variants. The discovery of an ELF-variant of ClOp adds to the growing list of the likes of Hive, Qilin, Snake, Smaug, Qyick and numerous others.

We know that ClOp operations have shown little if no slow-down since the disruption in June 2021. While the Linux-flavored variation of ClOp is, at this time, in its infancy, its development and the almost ubiquitous use of Linux in servers and cloud workloads suggests that defenders should expect to see more Linux-targeted ransomware campaigns going forward.

SentinelLabs continues to monitor the activity associated with ClOp. SentinelOne Singularity protects against malicious artifacts and behaviors associated with ClOp attacks including the ELF variant described in this post.
